Explain how AI would enhance your system

This system is using predefined rules to check patient allergy information. By the system knowing what the foods the patient is allergic to, it will create a preliminary assessment to pre diagnose the patient with the right medication to combat the allergy. The limitation to the system is that it will not go beyond the rules imposed on it. Yes, the system can pre-diagnose based on what the patient may be allergic to but what about the potential side effects, age, and demographics regarding the patient? The system doesn't add variability to the "if" and "else: python code. AI can add the variability into the code by outputting a pre diagnosis with a treatment plan. For example, if a patient has a peanut allergy, a method of treatment could be avoiding peanuts and epinephrine. With AI, it would provide not only medication but also treatment plans to possibly build tolerance such as Oral immunotherapy.

Identify Work System Components

I believe all health professionals working in the hospital can use this system to help diagnose and explain to patients their treatment plans. This would require on site training by a health IT professional to understand the system and how to better present said information to the patient regarding their diagnosis and what to do and what can be done to manage/improve their health. All in all, this will not replace the human component of a health professional – patient relationship but to help add time for the interactions (whether it be a checkup, post op, etc). I would like to see this system integrated into EHR platforms as a quick access point to view the files, of course protected by MFA's so that only verified personnel can access them. Outside of direct providers such as Physicians and Nurses, Pharmacists can be overseers along with others to make sure that the EHR is updated and accurate.

For this system to work, it would need the following information: What allergies do you have? What are the preexisting medication(s) and methods that they have used to address their allergies? Have there been any side effects to possible medications? Doing this would lessen the risk of error in the patient's health record.
